Applications

- Communications networks
- Mechanical & Electrical systems in buildings and along streets
- Wire layout in VLSI chip design

VLSI Chip Design

Given a collection of cells and a collection of nets, find a way to position the cells (*placement*) and run the wires for net connections (*routing*) so the wires are short with as few vias as possible, and the whole layout uses a minimum amount of area.

In the early 1600's, Pierre Fermat posed the problem:
Given a triangle, find the point in the plane such that the sum of the distances to the vertices is minimized.

■ Evangelista Torricelli solved this problem in 1659:

If all angles are less than 120°, then P is the point from which each side of the triangle subtends an angle of 120°, else it is the vertex of largest measure.

Epitaxia B&B

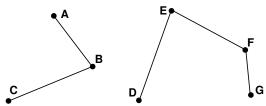

MDFDA

Annealing Evolution

Results

- A small search space is needed to **feasibly** complete the tree traversal, so we **prune** the tree:
 - **lower bound**: larger of $\frac{2}{3}$ RMST or $\frac{1}{2}$ perimeter
 - **upper bound**: RMST or result of heuristic
 - If collection of grid edges is
 - too large discard
 - too short discard
 - if they form a tree and it's shorter than current known tree, keep it
 - Unfortunately, there were still too many combinations to check

Implementation

Mat 3770 Steiner Trees

Overview

Spannin Trees

Grid

Kruskal

Naïve B&B

Pretaxial

Epitaxia B&B

MDFDA Annealing

Evolution

Results

All combinations of grid edges considered

Search Space: $O(2^{2n(n-1)})$ 3 points yield 2^{12} or 4096 combinations

- Implementation: essentially used a binary odometer where 1 = IN and 0 = OUT.
- Order the grid edges:

		-			_						а
0	0	0	0	0	0	0	1	1	0	1	0

The 1's at e, d, and b represent a forest containing those edges and no others.

 Determining whether the edges formed a tree (i.e., if they are connected) was very time consuming and the Search Space was too large.

Results

■ To aid in pruning, we can order both the points within the table as well as the lines for each point.

As we traverse the tree, we backtrack (prune) whenever our collection of lines:

- contains a line through each point (reached leaf)
- contains a cycle (too long)
- is longer than the best tree found so far (discard immediately)
- will never span the points (too short)

■ **Theorem.** The *Pretaxial* Branch and Bound search tree contains an SRSST over the set of points.

Spanning Trees

Kruskal

Naïve B&B

Ivalve D&L

Pretaxial B&B

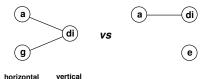

Epitaxia B&B

MDFDA

Annealing

Results

- How to determine whether the forest formed by edges from the table is **connected** (and thus a tree)?
- Since only horizontal and vertical lines can connect, these connections form a Bipartite Graph.
- Thus, vertices can be divided into two sets such that no two vertices in the same set are connected by an edge.
- Apply a depth-first search, marking vertices as they are visited. If all vertices are marked in that process, the tree is connected.

Epitaxial Approach — "Grow your own tree"

Results

When reducing the Search Space, be careful **not to eliminate** all optimal solutions: you must be able to show or prove at least one optimal solution still exists and will be found.

A possible heuristic: do a study to see where in the search tree Best is found. For example, an optimal solution for this problem was found in the first three branches of the root, so perhaps only look there. (The edges were ordered smallest to largest at each level.)

It may also be possible to **parallelize** the search — hand off subtrees to various processors to search and report back.

Heuristic Algorithms

Result

Idea: Using the Intersection pairs data structure, apply the Simulated Annealing algorithm (Kirkpatrick, Gelat & Vecchio) to the RSST Problem.

- Simulated Annealing is based on a strong analogy between the physical annealing process of solids and the process of solving large combinatorial optimization problems.
- Two phases of annealing:
 - **Melting** the solid so particles arrange themselves randomly
 - must have sufficiently high initial temperature.
 - Careful temperature reduction until particles arrange themselves in the ground state of the solid where the energy of the system is minimal

The Model

Mat 3770 Steiner Trees

Annealing

Evolution

Results

Two criteria for obtaining the ground state:

- Sufficiently high maximum temperature
- Sufficiently slow cooling schedule

To model the annealing process we need:

- Definition of a configuration, and an initial feasible solution described as such a configuration: Intersection Pairs.
- 2. A method for generating a **neighboring configuration**, which must also represent a feasible solution: **Randomly choose a pair to replace**.
- 3. A method for evaluating the **objective function** of the problem for any configuration: **length of tree**.
